

Lesson 24: Linear Inequalities in Two Variables

Criteria	4 - Exceeds Expectations	3 - Proficient	2 - Developing	1 - Needs Improvement
1. Boundary Line	Correctly identifies boundary line ($y = mx + b$) with perfect slope/intercept. Uses correct dashed/solid line style flawlessly.	Correct boundary line slope/intercept. Uses correct solid/dashed line 90% of the time.	Correct slope or intercept, but not both. Often confuses solid/dashed lines.	Incorrect boundary line and improper line style.
2. Shading Region	Consistently selects the correct half-plane, verified via a test point or slope-intercept form.	Selects correct half-plane, but may occasionally shade incorrect side due to error.	Struggles to identify which side to shade; shades arbitrarily.	Shading does not match the inequality sign.
3. Algebraic Form	Effortlessly rewrites inequality into slope-intercept form ($y \leq mx + b$), correctly handling negative signs.	Accurately rearranges into slope-intercept form with minor calculation errors.	Mismanages negative signs (e.g., forgets to reverse inequality sign when dividing).	Cannot rearrange inequality to isolate .

4. Interpretation	Clearly explains that the solution is a set of ordered pairs representing a region, not just the line.	Identifies that the solution is a region of ordered pairs.	Confuses boundary line with the shaded solution region.	Unable to interpret what the graph represents.
5. Accuracy	Graph is perfectly accurate, neat, and includes labeled axes and boundary line equation.	Graph is accurate but lacks neatness or labeling.	Minor errors in plotting points, leading to a shifted line.	Graph is fundamentally incorrect.
